

## **HETEROARYL-ETHANOLAMINE DERIVATIVES AS ANTIVIRAL AGENTS**

### **CROSS REFERENCE**

5           This application claims the benefit of the following provisional application: US  
Serial No 60/408,206, filed 9/4/2002 under 35 USC 119(e)(i), which is incorporated  
herein by reference in its entirety

### **FIELD OF THE INVENTION**

10           The present invention discloses five-(5) membered heteroaryl-ethanolamine  
derivatives, and more specifically, provides compounds of formula (I) described herein  
below. These compounds are useful as antiviral agents, in particular, as agents against  
viruses of the herpes family.

### **BACKGROUND OF THE INVENTION**

15           The herpesviruses comprise a large family of double stranded DNA viruses.  
They are also a source of the most common viral illnesses in man. Eight of the herpes  
viruses, herpes simplex virus types 1 and 2 (HSV-1 and HSV-2), varicella zoster virus  
(VZV), human cytomegalovirus (HCMV), Epstein-Barr virus (EBV), and human  
20   herpes viruses 6, 7, and 8 (HHV-6, HHV-7, and HHV-8), have been shown to infect  
humans.

          HSV-1 and HSV-2 cause herpetic lesions on the lips and genitals, respectively.  
They also occasionally cause infections of the eye and encephalitis. HCMV causes  
birth defects in infants and a variety of diseases in immunocompromised patients such  
25   as retinitis, pneumonia, and gastrointestinal disease. VZV is the causative agent of  
chicken pox and shingles. EBV causes infectious mononucleosis. It can also cause  
lymphomas in immunocompromised patients and has been associated with Burkitt's  
lymphoma, nasopharyngeal carcinoma, and Hodgkins disease. HHV-6 is the causative  
agent of roseola and may be associated with multiple sclerosis and chronic fatigue  
30   syndrome. HHV-7 disease association is unclear, but it may be involved in some cases  
of roseola. HHV-8 has been associated with Karposi's sarcoma, body cavity based  
lymphomas, and multiple myeloma.

Infection by or reactivation of herpesviruses is associated with several cardiovascular diseases or conditions in the host such as atherosclerosis and restenosis resulting in inflammation of coronary vessel walls. It is thought that in many patients suffering from restenosis following coronary atherectomy viral infection particularly by CMV plays an important role in the proliferation of the disease. Atherosclerosis is believed to be associated with the overall infectious disease burden in the host and particularly by the herpesviruses such as HSV, CMV, and EBV.

Infection in the animal population (livestock and companion) by strains of herpesviruses is endemic including cattle (Bovine herpesvirus 1-5, BHV), sheep (Ovine herpesvirus 1 and 2), dog (Canine herpesvirus 1), horse (Equine herpesvirus 1-8, EHV), cat (Feline herpesvirus 1, FHV), swine (pseudorabies virus, PRV), and many species of fowl. In the case of bovine herpesvirus infection, animals may suffer from ocular, respiratory, or digestive disorders. Pseudorabies is an extremely contagious viral pathogen infecting several species such as cattle, horses, dogs, cats, sheep, and goats leading to rapid death. The virus is benign in adult swine, however, it remains contagious and leads to high mortality in pigs under three weeks. Infection of horses by equine herpesvirus may lead to neurological syndromes, respiratory disease, and neonatal disease. Herpesvirus infection in cats leads to the disease known as feline viral rhinotracheitis (FVR) which is characterized by rhinitis, tracheitis, laryngitis, and conjunctivitis.

Due to the unique position of the five- (5) membered heteroaryl substituent on the formula I described herein below, compounds of the present invention demonstrate unexpected activity against the above reference herpesviral infections, particularly, human cytomegaloviral infection.

#### DETAILED DESCRIPTION OF THE INVENTION

5 For the purpose of the present invention, the carbon atom content of various hydrocarbon-containing moieties is indicated by a prefix designating the minimum and maximum number of carbon atoms in the moiety, i.e., the prefix C<sub>i-j</sub> indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus, for example, (C<sub>1-7</sub>)alkyl refers to alkyl of one to seven carbon atoms, inclusive, or methyl, ethyl, propyl, butyl, pentyl, hexyl, and heptyl, straight and branched forms thereof.

10 The term "halo" or "halogen" refers to the elements fluorine (F), chlorine (Cl), bromine (Br) and iodine (I).

The term "C<sub>3-8</sub>cycloalkyl" refers to a non-aromatic carbocyclic ring having from 3 to 8 carbon atoms.

15 The term "alkoxy" refers to the group RO-, wherein R is alkyl or cycloalkyl as defined above.

The term "heteroaryl" refers to aromatic heterocyclic groups.

It will be appreciated by those skilled in the art that compounds of the invention having a chiral center may exist in and be isolated in optically active and racemic forms. "Pharmaceutically acceptable salts" refers to those salts which possess the biological effectiveness and properties of the parent compound and which are not biologically or otherwise undesirable.

"Mammal" refers to human and animals. Animals specifically refer to, for example, food animals or companion animals.

"Optionally" or "may be" means that the subsequently described event or circumstance may, but need not, occur, and that the description includes instances  
5 where the event or circumstance occurs and instances in which it does not.

A "pharmaceutically acceptable carrier" means a carrier that is useful in preparing a pharmaceutical composition that is generally safe, non-toxic and neither biologically nor otherwise undesirable, and includes a carrier that is acceptable for veterinary use as well as human pharmaceutical use. "A pharmaceutically acceptable  
10 carrier" as used in the specification and claims includes both one and more than one such carrier.

Charts A-O describe the preparation of the compounds of Formula (I) of the present invention. All of the starting materials are prepared by procedures described in these charts, by procedures well known to one of ordinary skill in organic chemistry or can be obtained commercially. All of the final compounds of the present invention are prepared by procedures described in these charts or by procedures analogous thereto, which would be well known to one of ordinary skill in organic chemistry.

Compounds of Formula (I) are prepared as described in Chart A. Compounds of the formula A.1 in which X is a leaving group (e.g. mesylate, chloride, or bromide) are treated with a secondary amine of the formula  $R^4R^5C(OH)CH_2NH(R^3)$  in the presence of a non-nucleophilic base (e.g. diisopropylethylamine) in a polar solvent (e.g. DMF) to afford products of the formula A.2. It would be understood by those skilled in the art that in some cases transient protection of hydroxyl and other Lewis basic or acidic functionality present in  $R^4R^5C(OH)CH_2NH(R^3)$  may be required to facilitate the coupling described in Chart A for which procedures are well established (Greene, T. W.; Wuts, P. G. M. *Protective Groups in Organic Synthesis*, 1999).

#### CHART A

Alternatively, compounds of Formula (I) are prepared as described in Chart B. Compounds of the formula A.1 in which X is a leaving group (e.g. mesylate, chloride, or bromide) are treated with a primary amine of the formula  $R^4R^5C(OH)CH_2NH_2$  in the presence of a non-nucleophilic base (e.g. diisopropylethylamine) in a polar solvent (e.g. DMF) to afford products of the formula B.1. The resulting secondary amine is

then alkylated by reactions generally known by those skilled in the art such as (1) the reaction of B.1 with a corresponding alkylhalide, dialkylsulfonate, or alkylarylsulfonate or (2) the reaction of B.1 with an aldehyde (e.g. formaldehyde or acetaldehyde) in the presence of a reducing agent (e.g. sodium cyanoborohydride or sodium triacetoxyborohydride) to afford compounds of the general formula A.2.

CHART B

Alternatively, compounds of Formula (I) are prepared as described in Chart C. Compounds of the formula A.1 in which X is a leaving group (e.g. mesylate, chloride, or bromide) are treated with an alkyl primary amine (e.g. methylamine or ethylamine) in the presence of a non-nucleophilic base (e.g. diisopropylethylamine) in a polar solvent (e.g. DMF) to afford products of the formula C.1. The resulting secondary amine is then treated with an electrophile either of the formula  $R^4R^5C(OH)CH_2X$  (where X is Cl, Br) in the presence of a non-nucleophilic base (e.g. diisopropylethylamine) in a polar solvent (e.g. DMF) or with an epoxide to afford products of the formula A.2. Alternatively, compounds of the formula C.1 are alkylated with 2-haloketones of the formula  $R^4C(O)CH_2X$  (where X is Cl, Br) according to Chart D to afford products of the formula D.1. The resulting amino ketones are then reduced with an appropriate achiral or chirally-modified reducing agent (e.g.  $NaBH_4$  or diisopinocampheylchloroborane) to provide compounds of the formula A.2.

CHART C

CHART D

5

The precursors A.1 are available from the corresponding alcohols (Y = OH) by treatment with methanesulfonyl chloride in the presence of an organic base (e.g. pyridine or 2,4,6-collidine) and if needed an activating agent (e.g. DMAP), Chart E.

Alternatively, compounds of the formula A.1 are available by treatment of a tertiary amino derivative (e.g. Y = N(CH<sub>3</sub>)<sub>2</sub> or 4-morpholinyl) with ethyl chloroformate in an appropriate solvent (e.g. chloroform, dichloromethane, 1,2-dichloroethane, or benzene).

15

CHART E

20

Subsequently, compounds of the general formula E.1 are prepared according to procedures described in US patent 6,239,142 or exemplified in Charts F, G, and H below.

25

As described in Chart F, 3-bromo-2-chlorothiophene (F.1) is metalated with lithium diisopropyl amide in tetrahydrofuran at low temperature followed by addition to paraformaldehyde to provide alcohol F.2. The free hydroxyl is protected employing common methodology (Greene, T. W.; Wuts, P. G. M. *Protective Groups in Organic Synthesis*, 1999) such as the tert-butyldimethylsilyl ether (TBS) by treatment with the corresponding silyl chloride and a weak base (e.g. imidazole) in a polar solvent (e.g. DMF). Metalation of F.3 with *n*-butyl lithium followed by addition to *N*-methoxy-*N*-methylacetamide provides the methyl ketone F.4. Condensation of F.4 with diethyl carbonate in the presence of a strong base (e.g. sodium hydride) affords ketoester F.5.

30

Compound F.5 is then refluxed in a mixture of acetic anhydride and triethylortho-  
 formate to afford an intermediate enol ether which is then condensed with a primary  
 amine or aniline (e.g.  $R^2NH_2$ ) to provide a compound of the formula F.6. The  
 resulting enamines are cyclized by heating in the presence of a base (e.g. sodium  
 5 hydride, potassium carbonate, or potassium *tert*-butoxide) in an appropriate solvent  
 (e.g. THF, DMF, or *tert*-butanol) to provide F.7. Esters of the formula F.7 are  
 converted to amides of the general formula F.8 by either (a) treatment with a  
 substituted benzylamine (e.g. 4-chlorobenzylamine, 4-fluorobenzylamine, or 4-  
 bromobenzylamine) at high temperature or (b) saponification by treatment with an  
 10 inorganic base such as sodium hydroxide to afford the corresponding carboxylic acid  
 which is then coupled with a substituted benzylamine mediated by 1,1'-carbonyl-  
 diimidazole (or other suitable carboxylic acid activating agent). Subsequent  
 deprotection of the hydroxyl protecting group to afford E.1 is accomplished through  
 common procedures such as treatment with tetrabutylammonium fluoride in the case of  
 15 silyl ether protection.

## CHART F

Compounds of formula E.1 ( $Y = NR_2$ ) may be prepared as described in Chart G. 3-Bromo-2-chlorothiophene (F.1) is metalated with lithium diisopropyl amide in tetrahydrofuran at low temperature and condensed with *N,N*-dimethylformamide to afford the carboxaldehyde G.1. Reductive amination of G.1 by treating with an amine (e.g. morpholine), acetic acid, and an appropriate reducing agent (e.g. sodium triacetoxyborohydride) affords thiophenes of the formula G.2. Metalation of G.2 with *n*-butyl lithium followed by addition to *N*-methoxy-*N*-methylacetamide provides the methyl ketone G.3. Condensation of G.3 with diethyl carbonate in the presence of a strong base (e.g. sodium hydride) affords ketoester G.4. The resulting ketoester is then treated with a benzylamine (e.g. 4-chlorobenzylamine, 4-fluorobenzylamine, or 4-bromobenzylamine) in refluxing xylene to provide ketoamides of the formula G.5. Compound G.5 is then refluxed in a mixture of acetic anhydride and triethylorthoformate to afford an intermediate enol ether which is then condensed with a primary amine or aniline (e.g.  $R^2NH_2$ ) to provide a compound of the formula G.6. The resulting enamines are cyclized by heating in the presence of a base (e.g. sodium hydride, potassium carbonate, or potassium *tert*-butoxide) in an appropriate solvent (e.g. THF, DMF, or *tert*-butanol).

# CHART G

Alternatively, compounds of formula E.1 ( $Y = OH$ ) may be prepared as described in Chart H. Ethyl 4-hydroxythieno[2,3-*b*]pyridine-5-carboxylate (*J*.

*Heterocyclic Chem.* **1977**, *14*, 807) is metallated with from two to six equivalents of lithium diisopropylamide at low temperature and is then reacted with dimethylformamide to provide compound H.2. Treatment of H.2 with an appropriate reducing agent (e.g. NaBH<sub>4</sub>) in a polar solvent (e.g. ethanol) affords the alcohol H.3.

- 5 The resulting ester is then reacted with a substituted benzylamine (e.g. 4-chlorobenzylamine, 4-fluorobenzylamine, or 4-bromobenzylamine) at high temperature or under other common amide forming conditions well known to those skilled in the art to provide compounds of the formula H.4. Compound H.4 is alkylated at the ring nitrogen by treatment with an optionally substituted alkyl halide or alkyl sulfonate ester
- 10 in the presence of a base (e.g. potassium carbonate) or by reaction with an optionally substituted alkanol under Mitsunobu conditions to afford compounds of the general formula E.1. Specific examples of such alkyl halides used in this reaction include but are not limited to iodomethane, iodoethane, 1-iodopropane, 1-iodobutane, and 1-bromo-2-methoxyethane. It would be understood by those skilled in the art that in
- 15 some cases transient protection of hydroxyl functionality present in the R<sup>2</sup>X (X = halo or sulfonate) or R<sup>2</sup>OH reagent used in the above step may be required to facilitate the coupling described in Chart H or subsequent chemistry described in Charts A – E. Specific examples of such protected-hydroxyalkyl halides used in this reaction include but are not limited to 2-(2-bromoethoxy)tetrahydro-2*H*-pyran, 2-(3-
- 20 bromopropoxy)tetrahydro-2*H*-pyran, 4-(bromomethyl)-2,2-dimethyl-1,3-dioxolane, 2-(2-(2-chloroethoxy)ethoxy)tetrahydro-2*H*-pyran, and 2-(chloromethoxy)ethyl benzoate. Procedures to deprotect these cases at the final or intermediate stage are well established (Greene, T. W.; Wuts, P. G. M. *Protective Groups in Organic Synthesis*, 1999).

25

## CHART H

The amine  $R^4R^5C(OH)CH_2NH(R^3)$  in Chart A may be commercially available, can be prepared by procedures known to those skilled in the art, or can be prepared by methods illustrated in Charts I - O. As shown in Chart I, commercially available methylketones I.1 can be halogenated ( $X = Cl, Br$ ) to provide the haloketones of the formula I.2. The resulting haloketones can be reduced to yield the corresponding halohydrins I.3 employing either achiral (e.g.  $NaBH_4/CeCl_3$ ) or chiral reduction conditions (e.g. Hamada, T.; Torii, T.; Izawa, K.; Noyori, R.; Ikariya, T. *Org. Lett.* **2002**, *4*, 4373-4376). The resulting halohydrin is then treated with a primary amine (e.g. methylamine or ethylamine) to afford amines of the formula I.5. Alternatively, the haloketones can be treated directly with the primary amine (e.g. methylamine or ethylamine) to provide an aminoketone I.4 which can then be reduced under achiral or chiral reduction conditions (Ohkuma, T.; Ishii, D.; Takeno, H.; Noyori, R. *J. Am. Chem. Soc.* **2000**, *122*, 6510-6511; Kawamoto, A.; Wills, M. *Tetrahedron: Asymmetry* **2000**, *11*, 3257-3261) to afford compounds of the formula I.5. In this case, the basic nitrogen may require transient protection (e.g. *tert*-butylcarbamate) to facilitate the reduction. The precursor *N*-Boc aminoketones J.2 may be prepared as described in Chart J in which a Weinreb amide derivative ( $Y = N(CH_3)(OCH_3)$ ), prepared by methods well known in the literature, e.g. Sibi, M. *Org. Prep. Proc. Int.* **1993**, *25*, 15-40) is reacted with metalated *tert*-butyl dimethylcarbamate in the presence of tetramethylethylenediamine at low temperature. Other compounds of the formula J.1

which also undergo this reaction include carboxamides wherein Y = 4-morpholine and thiol esters (e.g. Y = SPh).

### CHART I

### CHART J

Alternatively, as shown in Chart K specific amines of the formula  $\text{R}^4\text{R}^5\text{C(OH)CH}_2\text{NH(R}^3\text{)}$  can be prepared from carboxaldehydes K.1 which are commercially available or prepared by methods known to those skilled in the art. Epoxidation of K.1 with a sulfonium ylide (e.g. trimethylsulfonium iodide) affords epoxides of the formula K.2. Treatment of the epoxides with a primary amine (e.g. methylamine or ethylamine) provides compounds of the formula I.5.

### CHART K

As shown in Chart L, specific amines of the formula  $\text{R}^4\text{R}^5\text{C(OH)CH}_2\text{NH(R}^3\text{)}$  are also prepared from carbonyl derivatives L.1 by the reaction with metalated *tert*-butyl dimethylcarbamate in the presence of tetramethylenediamine at low temperature

to afford the BOC-protected amino alcohol L.2. Subsequent cleavage under acidic conditions (e.g. trifluoroacetic acid or hydrochloric acid) or oxazolidinone cyclization under basic conditions (e.g. sodium hydride) followed by basic hydrolysis provides compounds of the formula L.3. In cases where R<sup>5</sup> is hydroxymethyl, 2-hydroxyethyl, or 1-hydroxyethyl, the hydroxyl group is transiently protected using common protecting groups (Greene, T. W.; Wuts, P. G. M. *Protective Groups in Organic Synthesis*, 1999) and then deprotected either prior to or after coupling as described in Chart A.

### CHART L

As shown in Chart M, specific amines of the formula  $R^4R^5C(OH)CH_2NH(R^3)$  are also prepared from a protected form of methylaminoacetaldehyde or methylaminoacetaldehyde (e.g. (methyl(trityl)amino)acetaldehyde) (M.1). Treatment of M.1 with a metalated heteroaryl reagent at low temperature affords alcohols of the formula M.2. Subsequent deprotection of the nitrogen protecting group (e.g. in the case of trityl, treatment with an inorganic acid in ethereal solution) provides amines of the formula I.5. It would be understood by those skilled in the art that in some cases transient protection of Lewis basic or acidic functionality present in the R<sup>4</sup> substituent may be required to facilitate the metal reagent formation and subsequent addition described in Chart L for which procedures are well established (Greene, T. W.; Wuts, P. G. M. *Protective Groups in Organic Synthesis*, 1999).

### CHART M

In cases where the R<sup>5</sup> substituent of the amine  $R^4R^5C(OH)CH_2NH(R^3)$  is methyl or ethyl, the amine may be prepared as described in Chart N. The olefin N.1 is

reacted with *N*-bromosuccinamide in an ether solvent employing a catalytic amount sulfuric acid to afford the bromohydrin N.2. The resulting bromohydrin is then treated with a primary amine (e.g. methylamine or ethylamine) to afford amines of the formula N.3.

# CHART N

Specific amines of the formula  $\text{R}^4\text{CH}(\text{OH})\text{CH}_2\text{NH}(\text{CH}_3)$  are also available from primary amines of the formula  $\text{R}^4\text{CH}(\text{OH})\text{CH}_2\text{NH}_2$  according to methods described in Chart O. An amino alcohol of the formula O.1 is treated with dimethyl carbonate and potassium *tert*-butoxide to afford an oxazolidinone of the formula O.2. The resulting oxazolidinone is subsequently hydrolyzed in the presence of aqueous alkali (e.g. potassium hydroxide) to provide an amino alcohol of the formula O.3.

# CHART O

Methods to prepare primary amines of the formula  $\text{R}^4\text{R}^5\text{C}(\text{OH})\text{CH}_2\text{NH}_2$  for use in Chart B are well known to those skilled in the art of organic synthesis (Bergmeier, S. C. *Tetrahedron* **2000**, *56*, 2561-2576). In addition to those described herein, representative synthetic examples include 2-amino-1-thien-2-ylethanol (Huebner, C. F.; Diassi, P. A.; Scholz, C. R. *J. Org. Chem.* **1953**, *18*, 21); 2-amino-1-(1*H*-indol-3-yl)ethanol (DeGraw, J. I.; Kennedy, J. G.; Skinner, W. A. *J. Heterocyclic Chem.* **1966**, *3*, 9); 2-amino-1-furo[2,3-*b*]pyridin-2-ylethanol, 2-amino-1-furo[2,3-*c*]pyridin-2-ylethanol, 2-amino-1-furo[3,2-*c*]pyridin-2-ylethanol, and 2-amino-1-furo[3,2-*b*]pyridin-2-ylethanol (Shiotani, S. *J. Heterocyclic Chem.* **1993**, *30*, 1035).

The compounds of Formula (I) may be prepared as single enantiomer or as a mixture of individual enantiomers which includes racemic mixtures. Methods to obtain

preferentially a single enantiomer from a mixture of individual enantiomers or a racemic mixture are well known to those ordinarily skilled in the art of organic chemistry. Such methods include but are not limited to preferential crystallization of diastereomeric salts (e.g. tartrate or camphor sulfonate), covalent derivatization by a  
5 chiral, non-racemic reagent followed by separation of the resulting diastereomers by common methods (e.g. crystallization, chromatographic separation, or distillation) and chemical reversion to scalemic compound, Simulated Moving Bed technology, or high/medium-pressure liquid chromatography employing a chiral stationary phase (Eliel, E. L. *Stereochemistry of Organic Compounds*, 1994; Subramanian, G. *Chiral*  
10 *Separation Techniques: A Practical Approach*, 2001). These techniques may be performed on the final compounds of Formula (I) or on any intermediates to compounds of Formula (I) which bear a stereogenic center. Also, to facilitate separation by any of the methods described above, the compounds of Formula (I) or any intermediates to the compounds of Formula (I) which bear a stereogenic center  
15 may be transiently reacted with an achiral reagent, separated, and then reverted to scalemic compound by standard synthetic techniques.

It will be apparent to those skilled in the art that the described synthetic procedures are merely representative in nature and alternative synthetic processes are known to one of ordinary skill in organic chemistry.

### Pharmaceutical Salts

The compound of formula I may be used in its native form or as a salt. In cases where forming a stable nontoxic salt is desired, administration of the compound as a pharmaceutically acceptable salt may be appropriate. Examples of pharmaceutically acceptable salts are organic acid addition salts formed with acids which form a physiological acceptable anion, for example, tosylate, methanesulfonate, acetate, citrate, malonate, tartarate, succinate, benzoate, ascorbate, ketoglutarate, and glycerophosphate. Suitable inorganic salts may also be formed, including hydrochloride, hydrobromide, sulfate, nitrate, bicarbonate, and carbonate salts.

Pharmaceutically acceptable salts may be obtained using standard procedures well known in the art, for example by reacting a compound of the invention with a suitable acid affording a physiologically acceptable anion.

Parenteral administrations include indirect injections to generate a systemic effect or direct injections to the afflicted area. Examples of parenteral administrations are subcutaneous, intravenous, intramuscular, intradermal, intrathecal, intraocular, intranasal, intraventricular injections or infusions techniques.

Topical administrations include the treatment of infectious areas or organs readily accessibly by local application, such as, for example, eyes, ears including external and middle ear infections, vaginal, open wound, skins including the surface skin and the underneath dermal structures, or other lower intestinal tract. It also includes transdermal delivery to generate a systemic effect.

The rectal administration includes the form of suppositories.

The transmucosal administration includes nasal aerosol or inhalation applications.

The preferred routes of administration are oral and parenteral.

Composition/Formulation

Pharmaceutical compositions of the present invention may be manufactured by processes well known in the art, *e.g.*, by means of conventional mixing, dissolving, granulation, dragee-making, levigating, emulsifying, encapsulating, entrapping, lyophilizing processes or spray drying.

Pharmaceutical compositions for use in accordance with the present invention may be formulated in conventional manner using one or more physiologically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. Proper formulation is dependent upon the route of administration chosen.

For oral administration, the compounds can be formulated by combining the active compounds with pharmaceutically acceptable carriers well known in the art. Such carriers enable the compounds of the invention to be formulated as tablets, pills, lozenges, dragees, capsules, liquids, solutions, emulsions, gels, syrups, slurries, suspensions and the like, for oral ingestion by a patient. A carrier can be at least one substance which may also function as a diluent, flavoring agent, solubilizer, lubricant, suspending agent, binder, tablet disintegrating agent, and encapsulating agent. Examples of such carriers or excipients include, but are not limited to, magnesium carbonate, magnesium stearate, talc, sugar, lactose, sucrose, pectin, dextrin, mannitol, sorbitol, starches, gelatin, cellulosic materials, low melting wax, cocoa butter or powder, polymers such as polyethylene glycols and other pharmaceutical acceptable materials.

Dragee cores are provided with suitable coatings. For this purpose, concentrated sugar solutions may be used which may optionally contain gum arabic, talc, polyvinyl pyrrolidone, carbopol gel, polyethylene glycol, and/or titanium dioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for identification or to characterize different combinations of active compound doses.

Pharmaceutical compositions which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as glycerol or sorbitol. The push-fit capsules can contain the active ingredients in admixture with a filler such as lactose, a binder such as starch, and/or a lubricant such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active

compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid paraffin, liquid polyethylene glycols, cremophor, capmul, medium or long chain mono-, di- or triglycerides. Stabilizers may be added in these formulations, also.

Liquid form compositions include solutions, suspensions and emulsions. For example, there may be provided solutions of the compounds of this invention dissolved in water and water-propylene glycol and water-polyethylene glycol systems, optionally containing suitable conventional coloring agents, flavoring agents, stabilizers and thickening agents.

The compounds may also be formulated for parenteral administration, *e.g.*, by injection, bolus injection or continuous infusion. Formulations for parenteral administration may be presented in unit dosage form, *e.g.*, in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulating materials such as suspending, stabilizing and/or dispersing agents.

For injection, the compounds of the invention may be formulated in aqueous solution, preferably in physiologically compatible buffers or physiological saline buffer. Suitable buffering agents include trisodium orthophosphate, sodium bicarbonate, sodium citrate, N-methylglucamine, L(+)-lysine and L(+)-arginine.

Parenteral administrations also include aqueous solutions of a water soluble form, such as, without limitation, a salt, of the active compound. Additionally, suspensions of the active compounds may be prepared in a lipophilic vehicle. Suitable lipophilic vehicles include fatty oils such as sesame oil, synthetic fatty acid esters such as ethyl oleate and triglycerides, or materials such as liposomes. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, the suspension may also contain suitable stabilizers and/or agents that increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, *e.g.*, sterile, pyrogen-free water, before use. For suppository administration, the compounds may also be formulated by mixing the agent with a suitable non-irritating excipient which is solid at room temperature but

liquid at rectal temperature and therefore will melt in the rectum to release the drug. Such materials include cocoa butter, beeswax and other glycerides.

For administration by inhalation, compounds of the present invention can be conveniently delivered through an aerosol spray in the form of solution, dry powder, or  
5 suspensions. The aerosol may use a pressurized pack or a nebulizer and a suitable propellant. In the case of a pressurized aerosol, the dosage unit may be controlled by providing a valve to deliver a metered amount. Capsules and cartridges of, for example, gelatin for use in an inhaler may be formulated containing a power base such as lactose or starch.

10 For topical applications, the pharmaceutical composition may be formulated in a suitable ointment containing the active component suspended or dissolved in one or more carriers. Carriers for topical administration of the compounds of this invention include, but are not limited to, mineral oil, liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene, polyoxypropylene compound, emulsifying wax and  
15 water. Alternatively, the pharmaceutical compositions can be formulated in a suitable lotion such as suspensions, emulsion, or cream containing the active components suspended or dissolved in one or more pharmaceutically acceptable carriers. Suitable carriers include, but are not limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, ceteary alcohol, 2-octyldodecanol, benzyl alcohol and water.

20 For ophthalmic and otitis uses, the pharmaceutical compositions may be formulated as micronized suspensions in isotonic, pH adjusted sterile saline, or preferably, as solutions in isotonic, pH adjusted sterile saline, either with or without a preservative such as a benzylalkonium chloride. Alternatively, for ophthalmic uses, the pharmaceutical compositions may be formulated in an ointment such as petrolatum.

25 In addition to the formulations described previously, the compounds may also be formulated as depot preparations. Such long acting formulations may be in the form of implants. A compound of this invention may be formulated for this route of administration with suitable polymers, hydrophobic materials, or as a sparingly soluble derivative such as, without limitation, a sparingly soluble salt.

30 Additionally, the compounds may be delivered using a sustained-release system. Various sustained-release materials have been established and are well known by those skilled in the art. Sustained-release capsules may, depending on their chemical nature, release the compounds for 24 hours or for up to several days.

### Dosage

Pharmaceutical compositions suitable for use in the present invention include compositions wherein the active ingredients are contained in an amount sufficient to  
5 achieve the intended purpose, *i.e.*, the treatment or prevention of infectious diseases. More specifically, a therapeutically effective amount means an amount of compound effective to prevent, alleviate or ameliorate symptoms of disease or prolong the survival of the subject being treated.

The quantity of active component, that is the compound of this invention, in the  
10 pharmaceutical composition and unit dosage form thereof may be varied or adjusted widely depending upon the manner of administration, the potency of the particular compound and the desired concentration. Determination of a therapeutically effective amount is well within the capability of those skilled in the art. Generally, the quantity of active component will range between 0.5% to 90% by weight of the composition.

15 Generally, an antiviral effective amount of dosage of active component will be in the range of about 0.1 to about 400 mg/kg of body weight/day, more preferably about 1.0 to about 50 mg/kg of body weight/day. It is to be understood that the dosages may vary depending upon the requirements of each subject and the severity of the viral infection being treated.

20 The desired dose may conveniently be presented in a single dose or as divided doses administered at appropriate intervals, for example, as two, three, four or more sub-doses per day. The sub-dose itself may be further divided, *e.g.*, into a number of discrete loosely spaced administrations; such as multiple inhalations from an insufflator or by application of a plurality of drops into the eye.

25 Also, it is to be understood that the initial dosage administered may be increased beyond the above upper level in order to rapidly achieve the desired plasma concentration. On the other hand, the initial dosage may be smaller than the optimum and the daily dosage may be progressively increased during the course of treatment depending on the particular situation. If desired, the daily dose may also be divided  
30 into multiple doses for administration, *e.g.*, two to four times per day.

In cases of local administration or selective uptake, the effective local concentration of the drug may not be related to plasma concentration and other procedures known in the art may be used to determine the desired dosage amount.

## BIOLOGICAL DATA

While many of the compounds of the present invention have shown activity against the CMV polymerase, these compounds may be active against the cytomegalovirus by this or other mechanisms of action. Thus, the description below of these compounds' activity against the CMV polymerase is not meant to limit the present invention to a specific mechanism of action.

The compounds of the present invention have shown activity in one or more of the assays described below. All of these assays are indicative of a compound's activity and thus of its use as an anti-viral agent.

The HCMV polymerase assay is performed using a scintillation proximity assay (SPA) as described in several references, such as N.D. Cook, et al., Pharmaceutical Manufacturing International, pages 49-53 (1992); K. Takeuchi, Laboratory Practice, September issue (1992); US Patent No. 4,568,649 (1986); which are incorporated by reference herein. Reactions are performed in 96-well plates. The assay is conducted in 100  $\mu$ l volume with 5.4 mM HEPES (pH 7.5), 11.7 mM KCl, 4.5 mM MgCl<sub>2</sub>, 0.36 mg/ml BSA, and 90 nM <sup>3</sup>H-dTTP. Assays are run with and without CHAPS, (3-[(3-Cholamidopropyl)-dimethylammonio]-1-propane-sulfonate) at a final concentration of 2 mM. HCMV polymerase is diluted in enzyme dilution buffer containing 50% glycerol, 250 mM NaCl, 10 mM HEPES (pH 7.5), 100  $\mu$ g/ml BSA, and 0.01% sodium azide. The HCMV polymerase, which is expressed in recombinant baculovirus-infected SF-9 cells and purified according to literature procedures, is added at 10% (or 10  $\mu$ l) of the final reaction volume, i.e., 100  $\mu$ l. Compounds are diluted in 50% DMSO and 10  $\mu$ l are added to each well. Control wells contain an equivalent concentration of DMSO. Unless noted otherwise, reactions are initiated via the addition of 6 nM biotinylated poly(dA)-oligo(dT) template/primer to reaction mixtures containing the enzyme, substrate, and compounds of interest. Plates are incubated in a 25 °C or 37 °C H<sub>2</sub>O bath and terminated via the addition of 40  $\mu$ l/reaction of 0.5 M EDTA (pH 8) per well. Reactions are terminated within the time-frame during which substrate incorporation is linear and varied depending upon the enzyme and conditions used, i.e., 30 min. for HCMV polymerase. Ten (10)  $\mu$ l of streptavidin-SPA beads (20 mg/ml in PBS/10% glycerol) are added following termination of the reaction. Plates are incubated 10 min. at 37 °C, then equilibrated to room temperature, and counted on

a Packard Topcount. Linear regressions are performed and  $IC_{50}$ 's are calculated using computer software.

5 A modified version of the above HCMV polymerase assay is performed as described above, but with the following changes: Compounds are diluted in 100% DMSO until final dilution into assay buffer. In the previous assay, compounds are diluted in 50% DMSO. 4.5 mM Dithiothreitol (DTT) is added to the polymerase buffer. Also, a different lot of CMV polymerase is used, which appears to be more active resulting in a more rapid polymerase reaction.

10 Results of the testing of compounds of the present invention in this assay are shown in Tables 1 below.

All results are listed as Polymerase  $IC_{50}$  ( $\mu$ M) values. In Table 1, the term "n.d." refers to activity data not determined.
